

The Mitsue Project

A Forest, a School, and a Future Powered by Itself

A Village in the Mountains of Nara

Mitsue sits deep in the mountains of Nara Prefecture — a quiet village of cedar slopes, clear water, and an aging community. Like hundreds of villages across rural Japan, it has watched its young people leave for the cities, its school close, and its forests grow heavy with sugi cedar planted in a different era.

The closed Mitsue Elementary School stands as a familiar symbol: a beautiful building, full of memory, waiting for a new purpose.

We believe it can become something remarkable.

A Simple Idea, Carefully Built

The Mitsue Project is a 25-year initiative to turn an abandoned school into a living example of how rural Japan can power its own future.

We will:

- **Restore native forests** in place of aging sugi monoculture, healing land that has been ecologically depleted for generations.
- **Build EV charging infrastructure** with privately owned solar panels and biomass-electric generation from forest thinning — energy resilience that belongs to the village, keeping it powered during blackouts and ready for the coming EV transition. Battery storage to be evaluated in the feasibility study.
- **Build a small, sustainable AI data center** inside the old school — powered entirely by that local energy, providing digital infrastructure where it has never existed before.

Three things, woven together: ecology, energy, and the digital age.

Why 25 Years

We are not building for the short term. The forests we plant will mature over decades. The technology we install will evolve. By the time our project completes its first full cycle, **localized small-scale fusion energy** may finally be commercially available — and the solar, biomass-electric, and EV infrastructure we build now will have served as the bridge.

In the meantime, we expect the world around Mitsue to change profoundly. Within ten years, most cars in Japan will be electric. Rural villages will need their own clean power, generated locally, to serve a future that the existing grid cannot reach.

The Mitsue Project is designed for that future.

Built on Citizen Science and Open Values

The project grows out of more than two decades of work with **Safecast**, the global open citizen science network for environmental monitoring, founded after the 2011 Fukushima disaster. The same values that made Safecast possible — open data, community ownership, and patient long-term commitment — shape everything about the Mitsue Project.

All environmental, energy, and forestry data from the project will be **published openly**. Any village, anywhere in the world, will be able to learn from what we do here.

The People Involved

The project is led by **Rob Oudendijk**, a Dutch electrical engineer who has lived in Mitsue since 2012 and is a core hardware developer for Safecast.

Advising the project are:

- [Joi Ito](#) — former Director of the MIT Media Lab, long-time advocate for open networks and creative technology
- [Ray Ozzie](#) — software pioneer behind Lotus Notes and former Microsoft Chief Software Architect

A dedicated **non-profit organization** is being established to coordinate the project, bringing together local residents, village leaders, forestry experts, technology partners, and academic collaborators.

A Model, Not a One-Off

Mitsue is not the only village facing these challenges. Across Japan — and across rural communities worldwide — closed schools, aging forests, and shrinking populations are part of the same story.

By documenting everything we do as an open, replicable playbook, we hope the Mitsue Project becomes a starting point rather than an endpoint. If it works here, it can work elsewhere.

The Long Walk Begins

This is a project that begins with conversations — with neighbors, landowners, village leaders, and partners. It will be built slowly, carefully, and with deep respect for the community that has called these mountains home for generations.

We invite anyone who shares this vision to walk with us.

The Mitsue Project
